[57] **ABSTRACT**

A buoyant plastic body is formed with an upwardly sloping front end. Held in place against the sloping front end is a unit comprised of two forwardly projecting hooks. A pair of weight members are embedded in the lower portion of the body near the rear end thereof. In this way, an optimum approach angle for the hook unit is provided as the body is pulled toward a downed water fowl by means of a conventional fish-line. Two laterally spaced keels extend along the bottom of the body and add to the stabilized control provided by the weight members. Entanglement with reeds or other water weeds is minimized by a pair of laterally projecting wings at the front end.

15 Claims, 7 Drawing Figures
